

EUCOMM/KOMP-CSD 'Knockout-First' Genotyping

Introduction

The majority of animals produced from the EUCOMM/KOMP-CSD ES cell resource contain the Knockout-First-Reporter Tagged Insertion allele. As well as gene specific elements, the targeting cassette contains many common elements e.g. encoding beta-galactosidase (lacZ gene), neomycin-resistance (neo gene), FRT and loxP sites. Further details can be found on <http://www.knockoutmouse.org/about/eucomm>. The majority of cassettes will be either promoter driven where the neo gene contains its own promoter and is separated from the lacZ gene by a 3rd loxP site, or promoterless (PL) where the neo and lacZ genes are adjacent and there are only 2 loxP sites. These have further implications in our genotyping strategies detailed later.

Promotor driven line

Promotorless line

Animals containing the full Knockout-First mutant allele (Tm1a) above can be crossed to mice expressing Fip or Cre recombinase. The progeny from these mating may contain converted forms of the Tm1a allele known as Tm1b, Tm1c and Tm1d depending on the breeding strategy performed. In order to genotype animals generated from the EUCOMM/KOMP-CSD 'Knockout-First' ES cell resource, a combination of mutant assays looking for sequences occurring in the targeting cassette, and WT specific assays will need to be performed. We typically use real time qPCR and copy count the various alleles. This assay design sheet will give an outline of how to genotype these lines by gel based and qPCR based technologies, as well as including details of assays we have tried and tested.

Tnfrsf1a-Tm1a

Details for the tm1a allele can be found below

[http://www.mousephenotype.org/data/alleles/MGI:1314884/tm2a\(EUCOMM\)Wtsi/](http://www.mousephenotype.org/data/alleles/MGI:1314884/tm2a(EUCOMM)Wtsi/)

Types of alleles

Promotor driven lines

Tm1d created by action of Cre recombinase on Tm1c allele

Gel based genotyping

The gel based assays are normally run on the Qiagen QIAxcel. This is a capillary based system that provides clearer resolution and is quicker than running standard agarose gels. Different size ladders may be loaded onto runs depending on the fragment sizes being analysed. Typically samples are run with a 50-800bp size ladder.

PCR is performed using KAPA2G Fast Hotstart Readymix (2X), although alternatives may be used.

Generic 4 primer PCR mix

Tm1a gel based genotyping

Tm1a gel based assays are designed using a universal mutant reverse primer that sits in the sequence just after the 5' homology arm

5mut-R1 GAACTTCGGAATAGGAACTTCG

A forward primer is designed to the 5' homology arm and designed to give a mutant specific band, typically between 100-150bp that will only be present if the cassette is present.

A WT reverse primer is designed to the critical region and should give a product of >200bp. If the mutant cassette is present the product between the two primers is too large to PCR under standard conditions.

Tm1b gel based genotyping

Promotor driven genotyping

Tm1b alleles are produced by exposing tm1a alleles to cre recombinase which causes the deletion of Neo and the critical region.

If the deletion of the critical region has not occurred then a product is produced between the -Crit-WTF and the -3arm-WTR. Complete conversion by Cre will mean a product is produced from the LacZ-F and -3arm-WTR as the two primers now lie close enough to generate a PCR product under standard conditions. Run both the tm1a genotyping protocol to detect WT and tm1a alleles and the tm1b protocol to detect converted alleles.

Promotorless genotyping

PL-Tm1b (promotorless tm1b) mice are produced in a similar fashion but only the deletion of the critical region occurs and Neo is still present.

If the deletion of the critical region has not occurred then a product is produced between the Crit-WTF and the 3arm-WTR. Complete conversion by Cre will mean a product is produced from the SV40-FRT-F and 3arm-WTR as the two primers now lie close enough to generate a PCR product under standard conditions. This will not work for promotor driven lines as the presence of the 5' loxP site between the Neo and lacZ sequence causes this region to be removed by cre deletion. Run both the tm1a genotyping protocol to detect WT and tm1a alleles and the tm1b protocol to detect converted alleles.

Tm1c and Tm1d gel based genotyping

Tm1c genotyping

Tm1c alleles are produced by exposing tm1a alleles to flp recombinase which causes the deletion of Neo and LacZ sequences that are between the FRT sites.

The protocol for tm1a genotyping needs to be run. Both tm1a and tm1c alleles will produce a mutant specific product from -5arm-WTF and 5mut-R1. WT and tm1c alleles will produce PCR products from -5arm-WTF and Crit-WTR although the tm1c product will be around 200bp bigger due to the presence of the FRT-loxP part of the cassette. In addition to this a generic tm1c assay can be used. This uses the 5'CAS-F1 and 3'CAS-R1 primers run with an internal control. The tm1c allele produces a 218bp product.

Tm1d genotyping

Tm1d mice are produced by crossing tm1c animals with mice expressing cre recombinase. This causes the deletion of the critical region.

The tm1d allele produces a 174bp product from the 5'CAS-F1 and 3'LOXP-R1 primers. A tm1c allele will produce a larger product which includes the critical region sequence. If the critical region is very large then a gene specific primer lying in the critical region may be needed to detect it (Crit-WTR).

Gel based genotyping strategy summary

Primers to use											
	5'CAS-F1	5mut-R1	LacZ-F	SV40-FRT-F	3'CAS-R1	3'LOXP-R1	5arm-WTF	Crit-WTF	Crit-WTR	3arm-WTR	Comments
Tm1a + PL		✓					✓		✓		
Tm1b			✓					✓		✓	Run tm1a protocol to identify WT alleles
PL-Tm1b				✓				✓		✓	Run tm1a protocol to identify WT alleles
Tm1c	✓	✓			✓		✓		✓		Blue =separate reaction
Tm1d	✓					✓			✓		Run tm1a protocol to identify WT alleles

- **WT** Product between 5arm-WTF and Crit-WTR (product too big in tm1a).
- **Tm1a** Product between 5arm-WTF and 5mut-R1.
- **Tm1b** Product between LacZ-F and 3arm-WTR (product too big in tm1a but PCR product from Crit-WTF and 3arm-WTR is made).
- **Tm1b-PL** Product between SV40-FRT-F and 3arm-WTR (product too big in tm1a but PCR product from Crit-WTF and 3arm-WTR is made).
- **Tm1c** 218bp product between 5'CAS-F1 and 3'CAS-R1 made. Can also run tm1a protocol for a gene specific assay.
- **Tm1d** 174bp product produced from 5'CAS-F1 and 3'LOXP-R1. Larger product may be produced by tm1c.

qPCR based genotyping

Standard PCR is the amplification of DNA between a pair of primers. Quantitative PCR employs the same principal as standard PCR, although it actually monitors the progress of the DNA synthesis as it occurs. The progress of the reaction is measured by using a Taqman probe. This is a short DNA oligo that is complementary to part of the DNA sequence between the forward and reverse primers. At the 5' end of the probe there is a fluorescent reporter (R) and at the 3' end a quencher (Q). Whilst they are in close contact with each other there is no fluorescent signal.

As the forward primer is extended the reporter is cleaved from the probe resulting in a fluorescent signal being detected. Once the primer extends enough to release the quencher this signal is blocked. By using probes with different fluorescent signals multiple PCR assays can be multiplexed and run together.

PCR reaction plot

The number of cycles the PCR takes to reach a set threshold is known as the CT value. This is inversely correlated to the amount of template DNA in the sample.

e.g. CT 25 = 2 x template DNA

CT 26 = 1 x template DNA

CT above 30 = no template represented in the sample

CT value can be used to determine how many copies of a particular allele samples have.

qPCR assay types

All qPCR assays are FAM labelled and run in duplex with a VIC labelled internal control, Dot1l. There are 4 mutant qPCR assays based around the targeting cassette. They are as follows:

- | | |
|------------------------|--|
| : Neomycin assay | Designed around the sequence of the neomycin resistance cassette. |
| : LacZ assay | Designed around the sequence of the LacZ reporter. |
| : Promotor driven Tm1b | Designed to detect the recombined sequence when a promotor driven tm1a allele is converted to a tm1b allele. The forward primer is based on the region of sequence of the cassette between LacZ and Neo sequences just upstream of the 5' most loxP. This is not present in promotorless alleles. The reverse primer is based on sequence found in the 3' loxP region. |
| : FRT-loxP | Designed to detect the recombined sequence of the FRT and loxP area created when the Tm1a allele is Flp converted to the tm1c. The forward primer is based on the sequence of the 5' region upstream of the 5' FRT site which means this assay will only work for Tm1c/d. |

There are 2 WT qPCR assays based on WT sequence that may be lost in Tm1a/b/c/d alleles. They are as follows:

- | | |
|----------|---|
| : BP-LOA | Break Point loss of allele assay. This is based on WT sequence that is lost around the loxP sites of the synthetic cassette. This detects any cassette and should drop in copy number if a tm1a/b/c or d allele is present. |
| : CR-LOA | Critical Region loss of allele assay. This is based on the critical region sequence that is flanked by the two loxP sites. This will only drop in copy number if a tm1b or tm1d is present. |

Tnfrsf1a EPD0971_5_E01

MRC Harwell

qPCR based methods to distinguish alleles

Promotor Driven Tm1a

Promotorless Tm1a

Run either LacZ or Neo which will identify the cassette and the BP-LOA which will identify the correct line as this should drop in copy number if the cassette has replaced the WT allele. The critical region should be 2 copies and may be run to distinguish tm1a alleles from tm1b alleles. Both the promotor driven tm1b and FRT-loxP should not work as they detect recombined cassettes (tm1 b/c/d) not the complete cassette (tm1a).

Promotor Driven Tm1b

Promotorless Tm1b

For both promotor driven and promotorless lines a drop in the CR-LOA copy number identifies the correct gene has been targeted. For promotor driven lines if the CR drops and the promotor-tm1b assay calls positive by the same value as the drop then the allele has been fully converted to a tm1b. A drop in Neo and the CR-LOA also would signify the same thing. For promotorless lines just a drop in the CR is enough to identify a tm1b or d allele and the presence of Neo or LacZ indicates it is not a tm1d.

qPCR based methods to distinguish alleles continued

Tm1c

A positive result for FRT-loxP confirms a tm1c or d allele. Running the BP-LOA and a drop in copy number will confirm the correct line has been targeted. To distinguish between tm1c and a tm1d allele (below) the CR-LOA must also be run. A drop in copy number for the CR-LOA indicates a tm1d allele.

Allele conversions

The action of either Fip or Cre recombinase can be used to convert the KO 1st alleles described in this document. Both gel based and qPCR genotyping methods may be employed to detect animals carrying the DNA sequences coding for these proteins.

Cre genotyping

Cre gel based assays are run using primers specific to DNA sequences encoding Cre recombinase as well as a set of primers detecting a house keeping gene Slc40a1. These are run using the same cycling conditions as described in page 4.
